Empirical Model

1944 cross-section, OLS, cell i = office $\times$ kakari $\times$ position:

$$y_i = \beta_1 D_i + \beta_2 D_i \times \log(S_i + 1) + \beta_3 \log(S_i + 1) + \gamma_1 \log(P_i^{\text{same kyoku}} + 1) + \gamma_2 \log(P_i^{\text{other kyoku}} + 1) + \alpha_{ka} + \alpha_{pos} + \varepsilon_i$$

- y: internal arrivals from the same ka, from outside the own ka, and in total
- D: drafted men in the cell
- S: men in the team's own ka in 1942 (and still employed in 1944), at the cell's rank or one below, excluding men in the cell in 1944
- P: the same pool in other ka and other kyoku (supply further away)
- Robustness: PPML; pools defined by same occupation instead of rank; kyoku clustering
- Inference: clustered by ka (97); kyoku (6) as alternative; wild cluster bootstrap, Webb weights

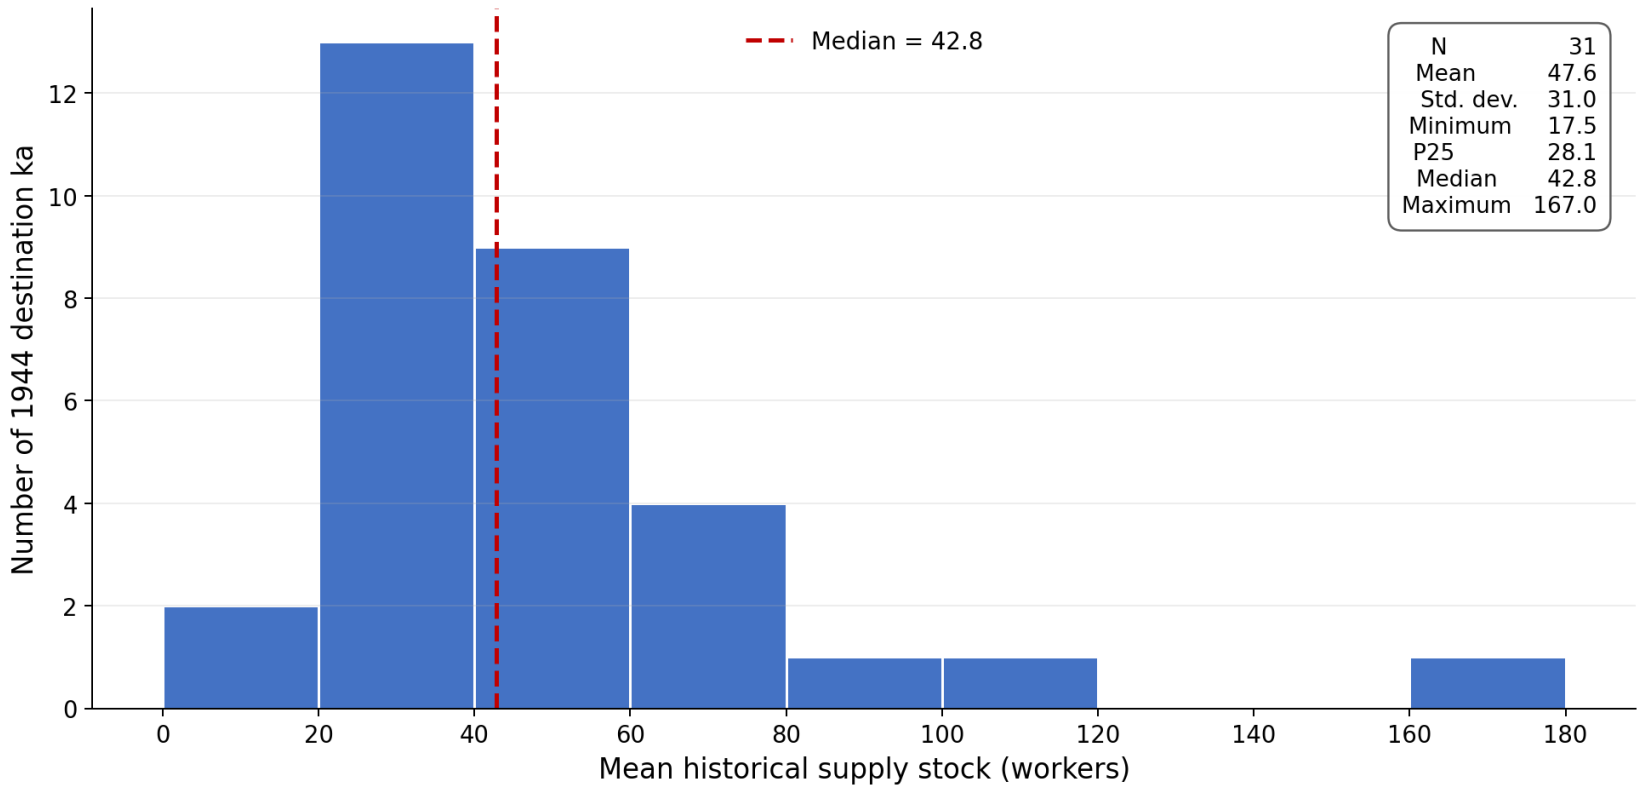

Hypothesis: $\beta_2 < 0$ for arrivals from outside the own ka.

Crosswalk Coverage and Historical Supply Stock

Coverage / stock match	Number
1944 ka with at least one drafted worker	80
Drafted ka represented in ground-truth crosswalk	47 (58.8%)
Ground-truth ka matched to a historical roster	43 (91.5%)
Ground-truth ka with positive mean historical stock	42 (89.4%)
Unique normalized ka names in ground truth	41
Unique drafted ka names with positive stock	31
Mean of office-level mean stock	42.9
Historical source labels matched	295 of 518

Corrected 1944 kyoku/ka assignments and expanded Tokyo Fu–Shi links are used. Historical stock is the mean annual roster count across all mapped 1938–1943 predecessor offices, counting named male staff still observed in 1944.

Summary Statistics for the 31 Matched Drafted Destination Ka

Notes: Distribution across 31 unique 1944 ka names with at least one drafted man and positive historical stock. Stock is the mean annual count across all mapped 1938–1943 Tokyo Fu and Tokyo Shi predecessor offices.

Duplicate ka names across bureaus are averaged by normalized ka name.
