Conscription and Workplace Adjustment: Reallocation, Hiring, and Long-Run Career Effects

- Conflicts and wars displaces workers from their workplaces.
  Japanese bill in 1945 mobilized 65% of the working population into the battlefields.
- Replacement costs for employers soar during wartimes
  - Internal markets: Younger staff are often abscent due to conscription.
  - External markets: Shortage of labor supply.

Research Questions

- How are the vacancies filled by reassinging incumbent workers into different roles through different contracts?
- What are the long run effect of such temporarly reassignment on the career trajectories of the colleagues surrounding the draftee?

Identifying who filled draft-induced vacancies

- We study how draft-induced vacancies in a public-sector organization with more than 40,000 employees (e.g., the Tokyo civil service) were filled.
- We compare vacancy-filling patterns across organizationally adjacent sections in response to draft-induced employee exits.
  - The drafting process was undisclosed to the public $\Rightarrow$ drafting is as good as random after conditioning on occupation and section assignment.
- We compare how vacancies are filled through internal transfers versus external hiring.

Natural departures and replacement margins: peace time

Natural departures, peace time, 1930–1936

	Internal staff response				*External*
	Total internal	— origin of worker — Retention (same section)	Same dept. (cross-section)	Diff. dept. (cross-bureau)	New hires
Internal-transfer departures	-0.061	0.248***	-0.092**	-0.217***	-0.101***
	(0.080)	(0.076)	(0.042)	(0.054)	(0.035)
Exit departures	0.359*	0.812***	-0.108**	-0.344***	0.039
	(0.187)	(0.246)	(0.051)	(0.105)	(0.045)
Observations			2,871		
Internal-transfer departures			1,460		
Exit departures			1,237		
Year FE			Yes		
Section FE			Yes		
Position FE			Yes		
Log cumulative male baseline			Yes		

Notes: OLS regressions. Unit of observation: destination office × kyoku × ka × kakari × occupation × year. Each row is estimated separately and reports the coefficient on the listed number of male natural departures from the same full cell between $t-1$ and t. Internal-transfer departures are workers observed in a different cell in t; exit departures are workers absent from the personnel directory in t. Draft-coded workers are excluded. Outcomes use the same replacement-margin definitions as the draft table. Standard errors clustered by office in parentheses. $^{***}p < 0.01$, $^{**}p < 0.05$, $^{*}p < 0.1$.

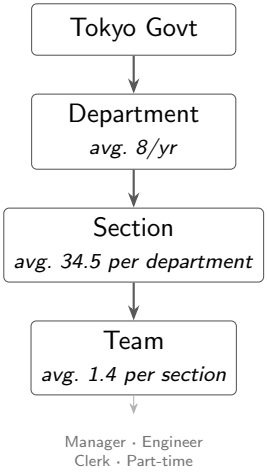

Natural departures and replacement margins: war time

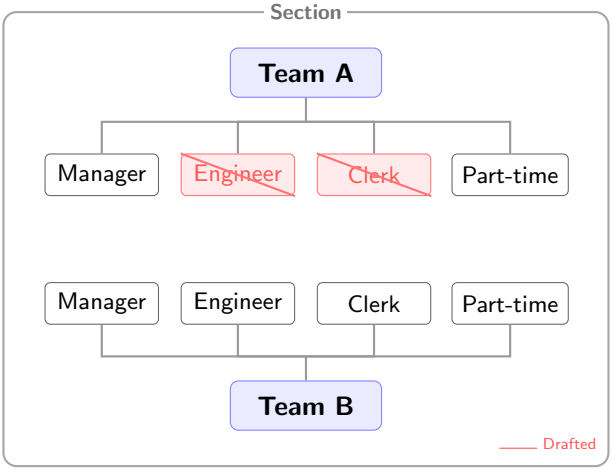

Natural departures, war time, 1937–1943

	Internal staff response				*External*

Exit departures			3,203		
Year FE			Yes		
Section FE			Yes		
Position FE			Yes		
Log cumulative male baseline			Yes		

Notes: OLS regressions. Unit of observation: destination office × kyoku × ka × kakari × occupation × year. Each row is estimated separately and reports the coefficient on the listed number of male natural departures from the same full cell between $t-1$ and t. Internal-transfer departures are workers observed in a different cell in t; exit departures are workers absent from the personnel directory in t. Draft-coded workers are excluded. Outcomes use the same replacement-margin definitions as the draft table. Standard errors clustered by office in parentheses. $^{***}p < 0.01$, $^{**}p < 0.05$, $^{*}p < 0.1$.

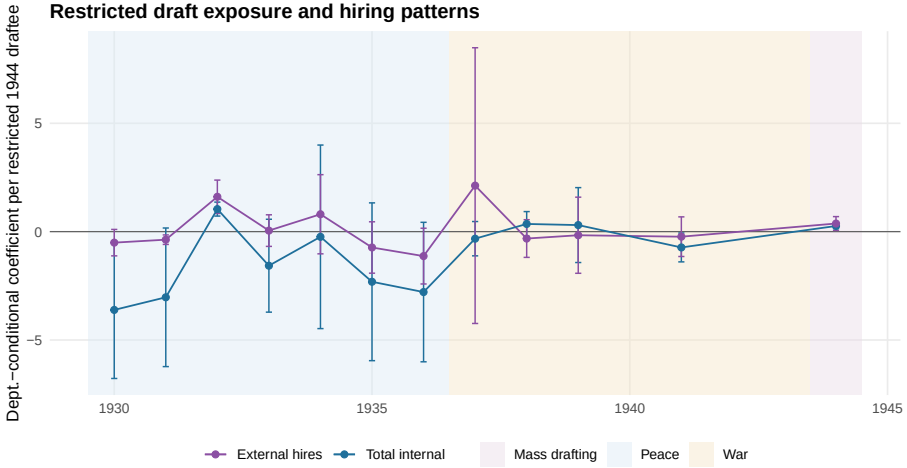

Identification: within-section, within-occupation

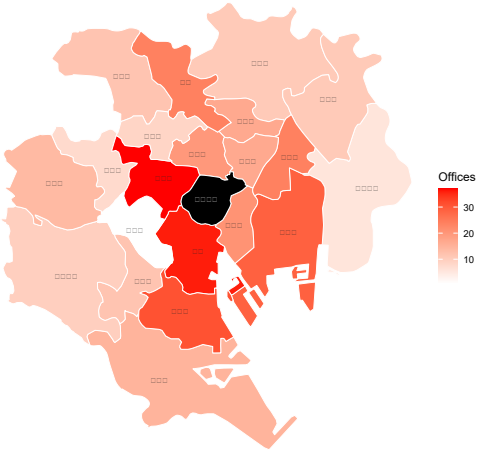

Balance test (backup)

Restricted exposure: baseline yearly correlations

Unit: office × team × occupation cells in offices with any restricted 1944 draft exposure. Estimates for 1930–1943 are baseline correlations; 1944 is the mass-drafting response year. Treatment is the 1944 male post-merger entrant draft count at the office × occupation level. Regressions condition on department and occupation and control for log cumulative male baseline.

Tokyo offices across wards

Empirical strategy: OLS with fixed effects

- For each hiring/transfer margin, we estimate:

$$Y_{okt} = \beta \cdot \text{Draftees}_{okt} + \theta \cdot \text{Workers}_{kt} + \alpha_o + \gamma_k + \varepsilon_{okt}$$

- Y_{okt}: hiring or transfer margin in occupation o, section k, and year t.
- Draftees_{okt}: number of drafted workers.
- Workers_{kt}: number of workers in section k in year t.
- α_o: occupation fixed effects.
- γ_k: section fixed effects.

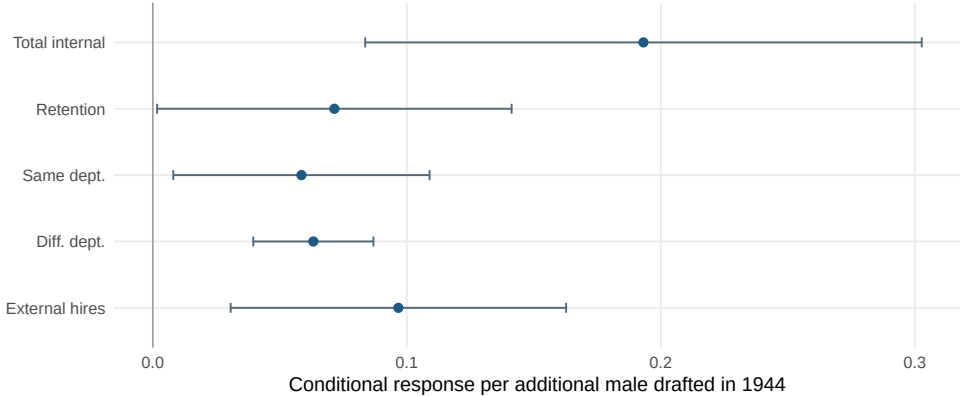

1944 draft margins: internal and external response

	Total internal	Retention	Same dept.	Diff. dept.	External hires
Male drafted workers	0.193***	0.071**	0.059**	0.063***	0.097***
	(0.056)	(0.036)	(0.026)	(0.012)	(0.034)
Observations			623		
Offices clustered			161		
Section and occupation FE			Yes		
Log cumulative male baseline			Yes		

Notes: OLS, 1944 only. Unit: observed destination office × team × occupation cell, with section identifiers retained. Outcomes exclude male workers marked drafted in 1944. Exposure is the male draft count in the same office-team-occupation cell. Cells without observed non-draftee outcomes are outside the sample. These are conditional associations, not identified causal replacement effects. Internal total includes retention, same-department transfers, and different-department transfers. Standard errors clustered by office. $^{***}p < 0.01$, $^{**}p < 0.05$, $^{*}p < 0.1$.

Internal / external $= 0.1932/0.0967 = \mathbf{2.00} : \mathbf{1}$.

1944 draft margins: decomposition

Internal total = retention + same−department + different−department transfers.
95% normal confidence intervals; standard errors clustered by office.

Draft margins: pooled 1938–1945 benchmark

	Total internal	Retention	Same dept.	Diff. dept.	External hires
Male drafted workers	0.408^{***}	0.227^{***}	0.100^{**}	0.081^{***}	0.206^{**}
	(0.076)	(0.073)	(0.040)	(0.015)	(0.100)
Observations			7,409		
Offices clustered			1,192		
Section and occupation FE			Yes		
Log cumulative male baseline			Yes		
Year FE			Yes		

Notes: OLS benchmark over the 1938–1945 window (observed directories: 1938–1944), with year fixed effects. Exposure is the contemporaneous male draft count; this is not a 1944-only estimate. Internal total includes retention, same-department transfers, and different-department transfers. Standard errors clustered by office. $^{***}p < 0.01$, $^{**}p < 0.05$, $^{*}p < 0.1$.

Internal / external $= 0.4079/0.2057 =$ **1.98** : **1**.

Post-merger entrant drafting: pooled benchmark

	Total internal	Retention	Same dept.	Diff. dept.	External hires
Male drafted workers	0.465*	0.221	0.096	0.148***	0.335
	(0.246)	(0.188)	(0.070)	(0.042)	(0.243)
Observations			7,409		
Offices clustered			1,192		
Section and occupation FE			Yes		
Log cumulative male baseline			Yes		
Year FE			Yes		

Notes: OLS over the 1938–1945 window (observed directories: 1938–1944), with year fixed effects. Exposure counts male post-merger entrants drafted in 1944; outcomes follow the pooled benchmark definition. Internal total includes retention, same-department transfers, and different-department transfers. Standard errors clustered by office. $^{***}p < 0.01$, $^{**}p < 0.05$, $^{*}p < 0.1$.

Internal / external $= 0.4651/0.3354 =$ **1.39** : **1**.

Further analysis

- How were promotions and bonus pay used to transfer or retain incumbent workers?
  Findings: Both were used more in impacted offices. Promotions were used more often together with transfers.
- How did early promotion help transferred workers in their subsequent careers?
  Findings:
  1. Transferees sent to drafted offices outperform those sent to non-drafted offices.
  2. Transferees from remote teams perform worse than transferees from neighboring teams.

Discussion and conclusion

- Workplaces compensated for staff losses jointly through internal and external markets (about 2:1 per drafted employee).
- These results support empirical work on responses to worker exits (Jaeger, Heining, and Lazarus, 2025; the worker-death paper).
  But we show that replacement costs varied with the composition of workers surrounding each affected worker.
- Transferred workers presumably accelerated promotion and contributed to better career trajectories.

References I

Empirical strategy: who is selected for transfer?

For each donor office unit-year, worker i chooses among transfer outcomes $j \in \{\text{stay}, \text{draft vacancy}, \text{non-draft vacancy}\}$:

$$\Pr(y_{it} = j \mid X_{it}) = \frac{\exp\left(X_{it}'\beta_j\right)}{\sum_{\ell \in \mathcal{J}} \exp\left(X_{it}'\beta_\ell\right)}, \qquad X_{it}'\beta_{\text{stay}} = 0.$$

$$X_{it}'\beta_j = \beta_{0j} + \beta_{1j}\text{Decor}_{i,t-1} + \beta_{2j}\text{Court}_{i,t-1} + \beta_{3j}\text{Female}_{it} + \beta_{4j}\text{Tenure}_{it} + \beta_{5j}\log(\text{Salary}_{i,t-1} + 1) + \lambda_{jt}.$$

- Outcomes are estimated separately for leaving at all, within-kyoku transfers, and cross-kyoku transfers.
- Decoration and CourtRank are coded 0–8, with 0 for unobserved status.
- Female is an indicator, Tenure is years since first observed, and λ_{jt} are outcome-specific year fixed effects.

Section FE			Yes		
Position FE			Yes		
Log cumulative male baseline			Yes		

Notes: OLS regressions. Unit of observation: destination office × kakari × occupation × year, 1938–1945. Each cell reports the coefficient on the number of drafted male workers in the same destination kakari-occupation-year. "Retention" counts workers who remained in the same ka group (same-section stayers). "Same dept." counts workers from a different ka group within the same normalized kyoku group (cross-section transfers). "Diff. dept." counts workers from a different normalized kyoku group (cross-bureau transfers). "Total internal" is the sum of all three. Panel B splits internal replacements by great-circle distance between prior-year and current-year office ward centroids. New hires exclude first observed office-years. All specifications include year, section, and position fixed effects and control for log cumulative male baseline employment. Standard errors clustered by office in parentheses. $^{***}p < 0.01$, $^{**}p < 0.05$, $^{*}p < 0.1$.

Peace-time cell departures and replacement margins

Tokyo-Shi baseline, 1929–1937

	Internal staff response				*External*

Natural male cell departures			3,742		
Year FE			Yes		
Section FE			Yes		
Position FE			Yes		
Baseline male employment (log)			Yes		

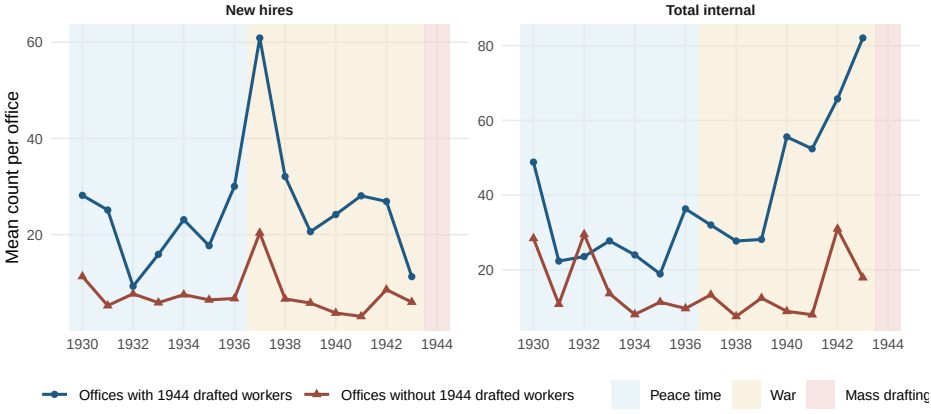

Notes: OLS regressions using Tokyo-Shi directory transitions, 1929–1937. Unit of observation: destination office × kyoku × ka × kakari × occupation × year. Observations are regression cell-years, not transfer counts. The treatment is the number of male workers in the same full cell in $t-1$ who are no longer in that exact cell in year t, excluding draft-coded rows. Outcomes use the same replacement-margin definitions as the wartime draft table: retention within the same ka group, transfers from a different ka group within the same normalized kyoku group, transfers from a different normalized kyoku group, and new hires excluding first observed office-years. All specifications include year, section, and position fixed effects and control for log cumulative male baseline employment. Standard errors clustered by office in parentheses. $^{***}p < 0.01$, $^{**}p < 0.05$, $^{*}p < 0.1$.

Placebo: future drafting and prior replacements

	Total internal	Retention	Same dept.	Diff. dept.	External hires
Male drafted workers	3.684***	2.000***	1.632*	0.052**	0.460***
	(1.043)	(0.525)	(0.912)	(0.022)	(0.150)
Observations			737		
Offices clustered			175		
Section and occupation FE			Yes		
Log cumulative male baseline			Yes		

Notes: Outcomes are 1943 replacement margins, excluding 1944 male draftees. Exposure is the future male draft count at each worker's actual 1943 location. Section and occupation FE; no year FE in this single-year placebo. Internal total includes retention, same-department transfers, and different-department transfers. Standard errors clustered by office. $^{***}p < 0.01$, $^{**}p < 0.05$, $^{*}p < 0.1$.

Office pre-trajectories: drafted offices

Descriptive

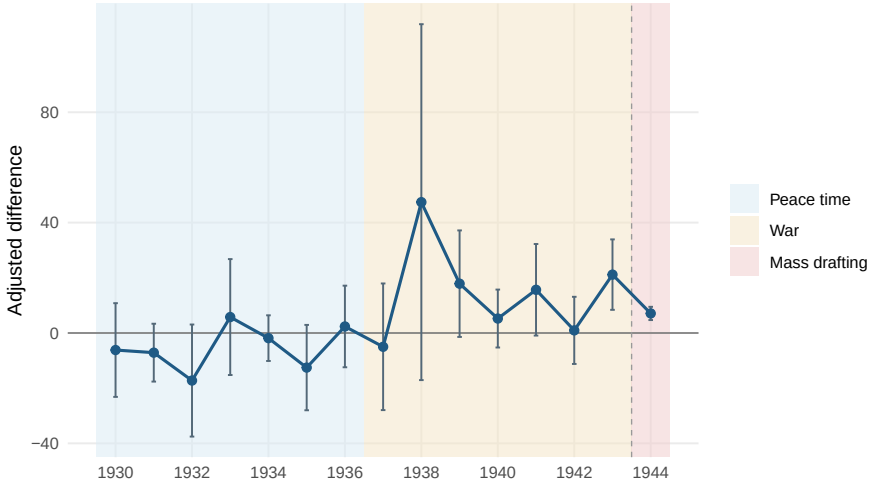

office-level 1930–1943 trajectories, grouped by whether the office contains any worker later marked drafted in the 1944 TokyoTo directory. Outcomes exclude those eventual draftees.

Pre-trends: adjusted office differences

	Adjusted difference: offices with 1944 drafted workers					
	1930	1933	1936	1939	1941	1943
Total internal	16.929	12.029	12.760*	11.945**	42.652***	58.037***
	(19.476)	(8.022)	(7.512)	(5.707)	(11.499)	(10.456)
Retention	-4.544*	0.450	9.348	2.730	22.992***	31.079***
	(2.353)	(0.478)	(6.298)	(1.889)	(7.217)	(8.077)

Back to identification slide

Research question idea: Tokyo bombing shock

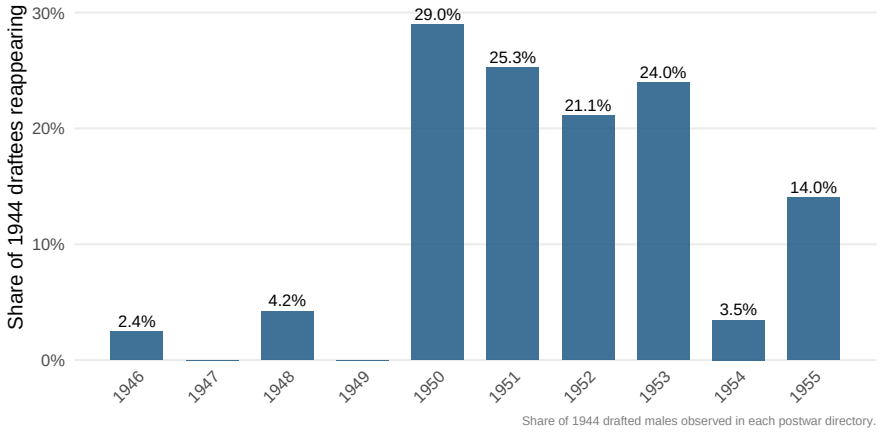

- How did the 1945 air-raid displace managers from teams?
- In 1947, Tokyo removed the bar for women to take managerial positions.
  $\Rightarrow$ Number of female managers increased from 10 to 100 in 1948.
- Did women managers get assigned to teams with a displaced manager?
- Did women managers retain/promote female employees more than male employees?

Did drafted workers return after the war?

	Basic OLS	Kyoku FE	Section FE
Drafted in 1944	0.4215***	0.4216***	0.4331***
	(0.0124)	(0.0158)	(0.0169)
Drafted return rate		42.3%	
Non-drafted exiter return rate		0.0%	
Drafted workers		1,849	
Non-drafted exiters (1944)		3,794	
Kyoku FE	No	Yes	—
Section FE	No	No	Yes
Controls (tenure, rank)	Yes	Yes	Yes

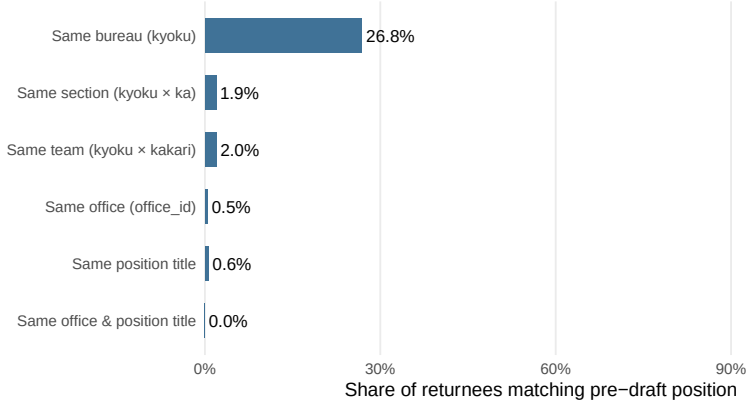

Notes: OLS regression. Outcome is an indicator equal to 1 if the worker is observed in any postwar directory (1947–1955). Sample is male workers whose last observed year is 1944 ("exiters"), so both groups left in 1944. "Drafted" workers are those flagged as drafted in the 1944 TokyoTo directory; the comparison group left for other reasons. Controls include years of tenure in 1944 and position rank. Standard errors clustered by office. $^{***}p < 0.01$, $^{**}p < 0.05$, $^{*}p < 0.1$.

When did drafted workers return?

Share of 1944 drafted males (N = 1,849) observed in each postwar Tokyo metropolitan government directory. No 1947 or 1949 directories available. The large spike in 1950 likely reflects the completion of demobilization and occupation-era restructuring.

Returnees: did they come back to the same position?

Among the 782 drafted workers who returned to Tokyo metropolitan government employment (1947–1955), the figure shows what share returned to the same organizational unit at each level of the hierarchy. Only 26.8% returned to the same bureau; virtually none (0.5%) returned to the same office. The 1943 Tokyo Fu/Shi merger and postwar reorganization largely dissolved the original structure.

Same-bureau return and postwar tenure

	Postwar years observed	
	(1) No FE	(2) Bureau FE
Same bureau (kyoku)	-0.018	0.227
	(0.111)	(0.153)
Bureau match rate	26.8% (N = 508 with non-missing kyoku)	
Observations	508	507
Bureau FE (pre-draft kyoku)	No	Yes
Pre-draft rank + years until return	Yes	Yes

Notes: OLS regressions. Sample: male 1944 draftees who returned to Tokyo metropolitan government employment in 1947–1955 (N = 782). "Same bureau" is an indicator equal to 1 if the worker's first postwar kyoku matches their 1944 kyoku. Match rates at finer levels (section, office, position title) are near zero (0.5–1.9%) due to the 1943 Fu/Shi merger and postwar reorganization. "Postwar yrs" counts postwar directories (1947–1955) in which the worker appears. Controls include years between 1944 and first postwar appearance and pre-draft position rank. Standard errors clustered by pre-draft office. $^{***}p < 0.01$, $^{**}p < 0.05$, $^{*}p < 0.1$.
